From Contigs To Scaffolds: Why?

REPETITIVE SEQUENCE

- Repetitive areas disturb the problem decisively
- Make contigs from reads exhibiting unique sequence
- Make scaffold of contigs, to bridge repetitive sequence

GENERATING CONTIGS

- De novo assembly programs usually deliver contigs
- Scaffolding requires data from additional, unconventional sources

Assembled Contigs: ACGATGCTCAGACCCC

[Lu, Shen, Warren and Walter, 2016]

Advantages:

- Removes redundancy among reads
- Easy to construct and store

Issues:

- looses information about linked mutations
- works only well with error-corrected reads

DE BRUIJN GRAPHS

SUMMARY

- Superior for NGS based consensus genome assembly
- For polyploid genome assembly: *colored de Bruijn graphs* (not treated here, but seem to have certain limitations)
- (Likely severe) limitations for polyploid genome assembly:
 - Error correction removes lowly frequent true mutations
 - Loose information about linked mutations

Overlap-Layout-Consensus

OVERLAP-LAYOUT-CONSENSUS (OLC)

- **Overlap**: Construct overlap graph from sequencing reads
- Layout: Compute *contigs*, longer stretches of overlapping reads using the overlap graph
- **Consensus**: Compute consensus sequence for contigs

OLC AND POLYPLOID GENOMES

SUMMARY

Advantages

- ► Edges ^{IS} overlapping reads from the same haplotype
- Error correction *after graph construction*

Disadvantages

- Overlap graph construction time and space consuming
- Error correction: new ideas required

Overlap Graph Construction

OVERLAP GRAPH CONSTRUCTION

Without reference genome

For each pair of reads, determine

- ► how they optimally overlap
- whether the resulting overlap indicates that the two reads are from the same haplotype (statistically significantly likely!)

Naive approaches infeasible!
